

Administrative Data | Agricultural Research Collection (AD|ARC)

Administrative Data | Agricultural Research Collection: 2021 – England

An Introductory Guide for Researchers

Version 1.2

29/04/2026

Authors

Dr Paul Caskie (Agri-Food and Biosciences Institute)

Sian Morrison-Rees (Swansea University/ADR Wales)

Laura Madden (Welsh Government/ADR Wales)

Sarah Lowe (Welsh Government/ADR Wales)

On behalf of the wider AD|ARC team and project partners: Matthew Curds (Welsh Government/ADR Wales), Maisie Duckham (DEFRA), Claire Greenwood (ADR UK Data Delivery at ONS), Rachael Loftus (Welsh Government/ADR Wales), Richard McFerran (Welsh Government/ADR Wales), Izzy Millward (ADR Data Linkage Team at ONS), Nathan O'Connor (ADR Data Linkage Team at ONS), Thomas Pearson (DEFRA) and Luke Williams (ONS ADR Data Acquisition Team).

Funding

This work is supported by ADR UK (Administrative Data Research UK), an Economic and Social Research Council (part of UK Research and Innovation) programme and by the Welsh Government.

Acknowledgements

The AD|ARC project in England notes with thanks the many collaborators who have supported the development of the Research Ready Dataset in England, including the Welsh Government, Public Health Wales, the AD|ARC Scientific Advisory Board and Stakeholder Reference Group, DEFRA, and the ADR Data Acquisition Team and ADR Data Linkage Team at ONS.

Similarly, the AD|ARC team notes with thanks the support of other data linking projects in the development this introductory guidance, most notably the Data First and ECHILD projects.

This report describes the Administrative Data | Agricultural Research Collection: 2021 – England which includes data from DEFRA, Rural Payments Agency and the ONS. These parties do not accept any responsibility for any inferences or conclusions derived by the authors.

Glossary of Terms and Acronyms

Basic Payment Scheme	The Basic Payment Scheme (BPS) replaced the Single Payment Scheme (SPS) in 2015 as a method of delivering direct subsidy payments to farmers. It began to be phased out in England in 2021 when it was subject to the first round of progressive cuts, with a 5% reduction applied to payments up to £30,000 and higher cuts above his threshold. A further round of payment reductions was applied in 2022. It officially closed on 31 st December 2023.
Beta Testing	Beta testing is the process of giving access to a dataset to a small subset of potential users to identify any problems before allowing wider access.
Blocking	Blocking means dividing a dataset into smaller groups based on a shared attribute to make matching more efficient. This limits the number of potential matches according to the blocking attribute, improving efficiency while maintaining accuracy. For instance, blocking on place of birth and sex means that a linking algorithm looking for Margaret Rutherford from Chalfont St. Peter would only search within the set of candidate matches of women born in that county.
Business ID	The Unique Identifier for Farm Businesses.
Business Structure Database	The ONS Business Structure Database provides a snapshot of a subset of data from the Inter-Departmental Business Register.
Cleaning	Data cleaning is the process of addressing incorrect, corrupted, incorrectly formatted, duplicate, or incomplete data in a dataset. Cleaning methods vary depending on the variable or dataset but may be as simple as fixing a clear typo to deleting invalid data altogether.
Data Dictionary	A Data Dictionary is a set of information describing the contents, format and structure of a dataset or database
Deterministic Matching	Deterministic Matching uses the exact correspondence between instances of an identifier or set of identifiers to produce a match. Deterministic matching assumes that unique identifiers such as names or dates of birth can be used to definitively link across datasets. Also see Probabilistic Matching.
Jaro-Winkler string comparisons	The Jaro–Winkler distance gives more favourable ratings to strings that match from the beginning for a set prefix length.
LSOA	Output Areas (OAs) are the lowest level of geographical area for census statistics and were first created following the 2001 Census. Lower layer Super Output Areas (LSOAs) are made up of groups of OAs, usually four or five. They comprise between 400 and 1,200 households and have a usually resident population between 1,000 and 3,000 persons. Using Census 2021 data, some changes were made to 2011 LSOAs due to population and household changes since 2011.
Matchkey	Matchkeys are a series of rules used in the matching process. They are usually fixed-length codes created from parts of names or addresses, and are designed so that similar variations produce the same matchkey.
Missingness	Missingness is the state of being missing and is usually applied to missing values, where no data value is stored within a variable for a particular case e.g. a farm business or a person living in a farming household.
Precision	‘Precision’ is a term used in the matching process and refers to the proportion of predicted links that are determined to be true matches.

	For example, if you predict 100 links between records and 90 of them are true matches, the precision is 0.9 (or 90%).
Probabilistic Matching	The process of using statistical analysis to determine the overall likelihood that two records match. Probabilistic matching is the preferred method for matching large data sets when unique identifiers such as names or dates of birth are unavailable or are not of sufficient quality to be used to definitively link across datasets. Also see Deterministic Matching.
Recall	'Recall' refers to the proportion of true matches found in the matching process. For example, if there are 100 true matches and 80 are found in the linkage process, the recall is 0.8 (80%).
Research Ready Dataset (RRD)	The term 'research ready data' is used to communicate the processing of administrative data to make it available for research. ADR UK defines a research ready dataset as follows: 'a dataset that is deemed 'research-ready' is expected to meet a minimum standard of documentation and be suitably de-identified to protect individuals' privacy, so it can be used for secure research'.
Secure Research Service (SRS)	The ONS Secure Research Service (SRS) is a DEA (Digital Economy Act 2017)-accredited Trusted Research Environment. The ONS SRS gives accredited/approved researchers access to de-identified, unpublished data to work on research projects for the public good.
UPRN	The Unique Property Reference Number or UPRN is the unique identifier for every addressable location across the UK.

1 What is the aim of this guide?

This user guide is intended to support researchers in seeking access to the Administrative Data | Agricultural Research Collection: 2021 – England. It provides an overview of the Dataset, including information on data content, quality, and security.

The guide also provides guidance on the processes required to access the Collection in England. This includes the process of becoming an accredited researcher, guidance on how to access the Secure Research Service (SRS) and the research governance processes to seek approval for access to the AD|ARC England 2021 RRD for specific research projects. Links to the AD|ARC Data Dictionaries are also included.

2 What is the Administrative Data | Agricultural Research Collection: 2021 – England?

The Research Ready Datasets (RRDs) have been created as part of the AD|ARC project. The aim of the project is to integrate the human dimension of farming with data on farming activities, to better understand the demographic, health, education, and economic characteristics of farm households associated with different types and sizes of farm businesses. It is hoped this will provide the insight decision makers need to formulate better policy for the Sector, thereby enhancing the wellbeing of farmers and their households across the UK.

AD|ARC links de-identified electronic records that are already collected by departments across the governments of the UK. Although administrative data is collected for non-statistical reasons, it can be hugely valuable for research. It provides rich sources of information that can be used in quantitative analysis and evaluation without imposing an additional burden on data subjects or additional costs on data controllers.

There are two AD|ARC datasets for England. Documentation for the first AD|ARC dataset (Agricultural Research Collection – England (ARCE) 2011) is available [here](#).

The AD|ARC England 2021 RRD, which is the focus of this user guide, includes variables from the following sources:

- ONS Census of Population for England and Wales 2021
- June Survey of Agriculture and Horticulture 2021
- Rural Payments Agency (RPA) 2020-2022
- Business Structure Database (BSD) 2008-2023

It should be noted that the AD|ARC Project Team have not carried out any imputation on the datasets. However, imputation of various kinds may have been carried out by the original data owners.

The AD|ARC England 2021 cohort is defined as: **all members of households in England that have been successfully linked to farm businesses claiming under the Basic Payment Scheme (BPS) in 2021.**

The cohort includes households where no individual had reported their main occupation as 'farming' in the Census 2021. However, we have included these households in the cohort because they lived at an address for which a farm business received a subsidy payment under the BPS in 2021.

This means that the cohort contains both:

- households where at least one individual reported an agricultural main occupation in the Census 2021; and
- households where no-one reported an agricultural main occupation in the Census 2021.

Because both types of households will have received subsidy payments, both are considered 'farming households' for analysis purposes.

The cohort includes every household member irrespective of age, including children.

However, it should be noted that farm businesses who chose not to claim BPS subsidies for which they were eligible will not appear in the RRD. Furthermore, where there was a second household residing at a different address, such as adult offspring who have moved but are still part of the business, they will not be included unless their address was also provided in the BPS application.

The AD|ARC England 2021 RRD consists of an Individual-Level Table and a Household-Level Table, each of which is briefly described below. The methodology to produce these Tables is described in Section 3 of this User Guide.

2.1 The Individual-Level Tables

There are four individual-level tables for the AD|ARC England 2021 RRD – the table relating to the cohort of individuals living in 'farming households' ([Table Name]_ADARC_2021_Person) and a table for each of four control groups.

The ([Table Name]_ADARC_2021_Person) includes individual-level records for all household members included in the cohort, allowing analysis to be conducted with the individual as the primary unit of analysis. The Table includes:

- the 2021 Census variables for each individual, e.g. age, gender, approximated social grade, National Statistics Socio-economic Classification, highest level of educational qualification, self-reported general health, whether the individual has a long-term health problem or disability etc.;
- selected agricultural variables, e.g. numbers of livestock, Utilised Agricultural Area etc.; and
- variables derived from the Census or agricultural sources, e.g. whether the individual reported their occupation as 'farming' on the Census, farm type, farm size etc.

The AD|ARC England 2021 [Data Dictionaries](#) include more detailed information about every variable in each dataset, including the variable type, the source of the variable (e.g. Census), the format in which the data is held and the magnitude of any missingness. As noted above, the methodology to produce these Tables is described in Section 3 of this User Guide.

In addition to the records for members of households linked to farm businesses ([Table Name]_ADARC_2021_Person), four further tables contain the following control groups:

- 1 individual per cohort member (i.e. per farming household member) matched on age (+/- 3 years), gender and Lower layer Surface Output Area (LSOA) as a proxy for rurality ([Table Name]_ADARC_2021_person_control)

- 1 individual per cohort member (i.e. per farming household member) matched on age (+/- 3 years), LSOA and employment status (e.g. self-employed) in the Census 2021 ([Table Name]_ **ADARC_2021_employment_control**)
- 1 individual per cohort member reporting their main occupation as farming (i.e. per self-reported 'farmer') matched on age (+/- 3 years), gender and a set of similar occupation codes in the Census 2021 ([Table Name]_ **ADARC_2021_occupation_control**).
- There is an additional table ([Table Name]_ **ADARC_2021_households_residents_control**) containing the residents for each household included in ([Table Name]_ **ADARC_2021_Household_control**).

([Table Name]_ **ADARC_2021_occupation_control**) includes individuals who self-report as farmers but do not meet our criteria to be included in the AD|ARC farming cohort - **all members of households in England that have been successfully linked to farm businesses claiming under the Basic Payment Scheme (BPS) in 2021**. The use of occupation codes allows researchers to distinguish between related but distinct economic activities.

Please note that individuals were selected for the control groups based purely on the individual characteristics listed above and not on either household size or household characteristics. So, for example, a female child living in an area with fewer than 2,000 residents may live with a lone parent in the control group but with two adults and three siblings in the cohort or vice versa. For example, this allows researchers to examine the relative household sizes of 'farming' households when compared with non-farming, rural controls.

For each matched control individual, the Table includes the same 2021 Census variables as for the cohort individual, however the fields for the agricultural variables are either not included or contain a null value.

2.2 The Household-Level Table

There are two household-level tables for the AD|ARC England 2021 RRD – the table relating to the cohort of farming households ([Table Name]_ **ADARC_2021_Household**) and a table for a control group ([Table Name]_ **ADARC_2021_Household_control**).

The ([Table Name]_ **ADARC_2021_Household**) includes household-level records for each farm business included in the cohort, allowing analysis to be conducted with the household as the primary unit of analysis. The Table includes:

- the 2021 Census variables that relate to the household and property e.g. the tenure of the dwelling, household size and composition, car/van availability, central heating etc.;
- variables relating to the farm business and activity data e.g. numbers of livestock etc.;
- variables derived from agricultural sources, e.g. farm type farm size etc.; and
- variables from the BSD, e.g. turnover.

There is a household level control group:

- 1 household (using Response_ID) from the Census 2021 per farming household matched via the LSOA for a similar geographical area ([Table Name]_ **ADARC_2021_Household_control**).

For each matched control household, the Table includes the same 2021 Census variables as for the cohort household, however the fields for the agricultural variables are either not included or contain a null value.

Please see the [Data Dictionary](#) for more information on the variables referred to above.

2.3 Supplementary Business Data Table

In addition to the individual- and household-level tables listed above, there is also ([Table Name] **ADARC_2021_BSD_supplemental**) which contains supplementary data from the BSD (e.g. counts of live PAYE records). This table may not be relevant to all projects but is available if needed.

2.4 Supplementary Census Relationship Data Table

In addition to the individual- and household-level tables listed above, there is also ([Table Name] **ADARC_2021_Census_relationship**) which contains supplementary Census 2021 relationship data. This table may not be relevant to all projects but is available if needed.

2.5 Supplementary Linking Table

In addition to the individual- and household-level tables listed above, there is also ([Table Name] **ADARC_2021_bridging**) which contains the CPH number, household ID number and Enterprise reference number (entref). This table may not be relevant to all projects but is available if needed.

3 How has the data been processed to produce the Administrative Data | Agricultural Research Collection: 2021 – England?

The Agricultural Research Collection: 2021 – England brings together datasets capturing information about farm households at four different levels:

1. Individual level – the individuals who make up farm households as identified by the resident_ID in the ONS Population Census 2021. There may be multiple individuals in each farm household.
2. Holding level – the June Survey of Agriculture and Horticulture records farm activities at a holding level identified by the County Parish Holding number (CPH).
3. Business level – the Rural Payments Agency data records payments made to farm businesses at a farm Business Level, identified by a Customer Reference Number. Some farm businesses in England have multiple holdings.
4. Household level – the households identified by the response_id in the Census 2021.

N.B. We have created a [synthetic dataset](#) for the [Wales 2011 RRD](#) that is highly comparable to the AD|ARC England 2021 RRD. The low fidelity synthetic dataset gives researchers the opportunity to assess if the real data will meet their needs before applying to access the real data.

Rural Payments Agency subsidies are paid at the farm business level. The June Survey of Agriculture and Horticulture is collected at the holding level. A farming household can have several farm business IDs. Equally, more than one farming household can be associated with a farm business. A farm business can have several holdings. However, each holding will have a distinct farm business ID (i.e. holdings are not split across farm businesses or farming households).

The steps below outline how this data has been processed to create the individual and household tables mentioned above.

3.1 Preparation of the data

Agricultural datasets (June Survey of Agriculture and Horticulture, and Rural Payments Agency) were sent from DEFRA to the ADR Data Linkage Team at ONS as separate datasets. A farm spine was created which allowed information from each table to be utilised when linking to Census 2021 and BSD.

As the 4 datasets are recorded at different levels of granularity, it was necessary to standardise the data such that they could be linked on common linkage variables. Each dataset was cleaned and standardized. Person and business names were extracted from contact names and address fields. Unique Property Reference Numbers (UPRNs), grid references, and dates of birth were standardized to enable matching of persons, households, and businesses across datasets.

More information is available in the Linkage Methodology Report prepared by the ADR Data Linkage Team at ONS. The full report will be made available to prospective users on the ADR website, and accredited researchers in their SRS project space.

3.2 Data Linkage between the Agricultural, business and Census 2021 data.

As noted above, the AD|ARC England 2021 RRD cohort is defined as: all members of households in England that have been successfully linked to farm businesses claiming under the BPS in 2021.

The ADR Data Linkage Team at ONS conducted the linkage and provided a report, summarised as follows:

A farm spine was created, comprised of June Survey of Agriculture and Horticulture (2021) and Rural Payments Agency (2020-2022) data. This farm spine was linked to both the Census (2021) and Business Structure Database (2020-2022) data. The data was linked using deterministic matching methods based on agreement of person, business and address information across the data sources.

Of the 105,220 June Survey of Agriculture and Horticulture records, 91,179 (86.7%) were linked to a Census person and/or household record and 102,991 (97.8%) were linked to an enterprise in the BSD.

Of 89,705 RPA subjects, 80,678 (89.9%) were linked to a Census person and/or household record and 83,072 (92.6%) were linked to an enterprise in the BSD.

The farm spine linked to the Census with 99.0% precision and 96.8% recall and to the BSD with 93.5% precision and 95.9% recall.

More information is available in the Linkage Methodology Report created by the ADR Data Linkage Team at ONS. The full report will be made available to prospective users on the ADR website, and accredited researchers in their SRS project space.

3.3 Construction of the AD|ARC England 2021 Research Ready Dataset

The data was de-identified and provisioned into the SRS for the project. The attribution data was provided in separate tables alongside the de-identified linkage tables. The project then used the linkage tables to construct the AD|ARC England 2021 RRD from the attribute tables to create an individual table and a household table. The household table includes the derived variables and variables aggregated to a household level (please see Figure 1, below, for a diagram of the linking process).

As noted in Section 1, ‘farmers’ who chose not to claim subsidies for which they were eligible, did not meet the eligibility criteria for subsidies, or lived at a second address not listed in the BPS application will not be included in the cohort.

Figure 1: Diagram of how the AD|ARC England 2021 RRDs were linked in the SRS

3.4 Aggregation of agricultural data to household level

As noted above, multiple Holdings and farm businesses can be linked to the same farm household. The June Survey of Agriculture and Horticulture and Rural Payments Agency variables have therefore been aggregated to the farm household level. Derived variables for a count of the number of holdings (num_cph) and farm businesses (num_entref) for each household are included in the dataset (see [Data Dictionary](#) for more information).

Farm Type has been recalculated at a household level using the same ‘[Robust Type 10](#)’ calculations and methodology used to calculate Farm Type in the June Survey of Agriculture and Horticulture.

As noted above, some farm businesses are linked to more than one household. Therefore, caution is required when aggregating farm business variables to avoid double-counting number of livestock, turnover etc.

4 Key Considerations for Research using the AD|ARC England 2021 Research Ready Dataset

All data has been linked and stored in either the Individual-level or the Household-level Tables ready for analysis (see accompanying [Data Dictionary](#)). Additional linking may be required for more complex research questions, but potential researchers should contact the AD|ARC Project Team who can advise on whether additional links are necessary and, if so, how to perform them.

Administrative data sources can be rich sources of information for research. However, because they are not designed specifically for research purposes, they often have limitations. Although the AD|ARC Project Team has undertaken the steps documented above to create a Research Ready Dataset, the following limitations should be kept in mind when both undertaking analysis and reporting findings:

- The dataset is 'research ready' in that we have linked together several different datasets to enable research. The data is, however, **not fully 'analysis ready'**. Researchers will still be required to assess the quality of the data and consider any necessary data preparation steps in accordance with their own research needs.
- The cohort **should not be seen as a census of all 'farming' households**. As noted in Sections 1 and 2.1, the cohort includes all members of households in England that have been successfully linked to farm businesses claiming under the BPS in 2021. 'Farmers' who chose not to claim subsidies for which they were eligible, did not meet the eligibility criteria for subsidies, or lived at a second address not listed in the RPA application will not be included in the cohort. This means that some individuals or households selected for the various AD|ARC control groups who have not stated a main occupation of farming in the 2021 Census may be involved in farming activities. This should be kept in mind when interpreting findings.
- The farm and Census datasets are **predominantly self-reported** which can lead to input error from spelling, formatting or missingness. The ADR Data Linkage Team at ONS report there is evidence in each of the original datasets that physical surveys or forms have been scanned into a computer, in some cases incorrectly, causing spelling errors. Fuzzy matching methods were conducted by the ADR Data Linkage Team at ONS to partially match the linkage variables available, allowing more matches to be made, albeit with slightly less confidence.
- There are numerous reasons why **data subjects may not be present across the original data sources** that were provided to the ADR Data Linkage Team at ONS. Therefore, it is likely that not all records were successfully linked. For example, the owner of a farm who was not living in the UK on 21st March 2021 will not be present in the underlying Census data. They will, however, be present in the underlying RPA data if they claimed BPS payments in 2022. Please see the Linkage Methodology Report, created by the ADR Data Linkage Team at ONS, for more details.
- There is **not a one-to-one relationship between farm holdings, businesses and individuals**. Multiple individuals can be associated with a farm holding, while multiple farm holdings (and therefore multiple individuals) may be associated with a business.

Individuals can also be associated with more than one farm holding and/or business. Flags have been allocated to records to indicate such scenarios (e.g. *duplicate_cph_to_subject_id*).

- The nature of farm businesses means that holdings, organisations and enterprises may have many-to-many relationships. Therefore, **some farm businesses are linked to more than one household**. Caution is therefore required when aggregating farm business variables. Potential researchers should seek advice from the AD|ARC Team.
- The BSD tables contain historical data relating to **businesses that may no longer be live and operational**. The ADR Data Linkage Team at ONS added a flag, *live_business*, to records for which a farm is linked to a live business. As well as the formatting and contents of the data available, some subjects' information will vary due to **data having been collected at different times**. Data for each type of RPA payment is recorded at different frequencies (e.g. once per year for the BPS, multiple times per year for Countryside Stewardship payments). The June Survey of Agriculture and Horticulture and Census data included in the AD|ARC England 2021 RRD were recorded on specific days in 2021, and the BSD is recorded quarterly.
- Farm businesses may make their BPS application through an **agent**. Records that may have incorrectly linked to an agent were allocated a flag, *agency_flag*, by the ADR Data Linkage Team at ONS. However, it is likely that some false links may have been made where the agency addresses were not labelled as such in the underlying data.

The ADR Data Linkage Team at ONS conducted quality assessments of their linkage work. The quality assessments include producing linkage metrics and drawing attention to potential bias by conducting proportional discrepancy analysis. Proportional discrepancy analysis involves highlighting where data subjects with certain characteristics may be under- or over-represented in the linked dataset. High-level findings from their analyses include:

- When linking farms to the Census 2021, the most overrepresented Robust Farm Type was Dairy farms and the most underrepresented were 'Specialist Poultry' and 'Horticulture'.
- While Very Small farms make up nearly 50% of the data, they are shown to be the most under-represented Robust Farm Type in the linked dataset.
- Farms with greater BPS value paid tend to be more over-represented in the business linkage.

More information is available in the Linkage Methodology Report created by the ADR Data Linkage Team at ONS. The full report will be [made available to prospective users on the ADR website](#), and accredited researchers in their SRS project space.

The challenges and limitations documented above should be taken into consideration by researchers when preparing their application to use the AD|ARC England 2021 RRD. The AD|ARC Project Team welcome queries and/or potential collaborations prior to an application for use of the data.

When researchers are writing reports based on the analysis of AD|ARC project data and need to add data quality indicators or commentary, they should feel free to quote the text from this User Guide.

The AD|ARC project datasets are complex and only just beginning to be used. Early research projects should therefore consider themselves beta-testers and should expect to find issues with the data. The Project Team would be grateful if projects could inform the

Team of any issues so, where possible, we can address them and, where not, we can provide appropriate documentation. Equally, this User Guide should be considered a 'starter for ten' and will be updated to include additional information or explanation where users ask the Project Team questions, so please do [get in touch!](#)

5 How is the Data Protected?

All the data held in the AD|ARC England 2021 RRD is de-identified. The associated data processing is administered under the framework outlined in the Digital Economy Act (2017) (DEA), which enables government to prepare administrative data for the purposes of research, and to provide de-identified versions of those data to researchers and projects accredited by the UK Statistics Authority (UKSA). The Secure Research Service is an accredited Trusted Research Environment under the DEA.

The Secure Research Service uses the Five Safes Framework to ensure the safety and security of its stored data. This is a set of principles adopted by a range of secure research environments to provide complete assurance for data owners. The Five Safes are:

- Safe People** – trained and accredited researchers are trusted to use data appropriately
- Safe Projects** – data are only used for valuable, ethical research that delivers clear public benefits
- Safe Settings** – access to data is only possible using secure technology systems
- Safe Outputs** – all research outputs are checked to ensure they cannot identify data subjects
- Safe Data** – researchers can only use data that have been de-identified

The AD|ARC England 2021 RRD is stored in the SRS. For more information about how data is de-identified and protected in the AD|ARC England 2021 RRD please follow the link below to SRS resources.

[ONS Secure Research Service](#)

6 How do I access the data?

Any researcher interested in accessing the AD|ARC England 2021 RRD is advised to [contact the AD|ARC Project Team](#) to discuss their proposal.

To apply to access the data, please see the guidance on the [Secure Research Service](#) website.

Prior to an application to the SRS, if not already DEA accredited, researchers will be required to complete the [ONS accredited researcher training](#).
